tridiagonal

Solves the tridiagonal linear system Ax = d for x using the tridiagonal matrix algorithm (i.e. the Thomas algorithm).

Syntax

```
x = tridiagonal(A,d)
```

Description

 $\mathbf{x} = \text{tridiagonal}(A,d)$ solves the tridiagonal linear system $A\mathbf{x} = \mathbf{d}$ for the vector $\mathbf{x} \in \mathbb{R}^n$, where $A \in \mathbb{R}^{n \times n}$ is a tridiagonal matrix and $\mathbf{d} \in \mathbb{R}^n$ is a vector.

Examples

Example 1

Solve the tridiagonal linear system Ax = d for x, where

$$\mathbf{A} = \begin{bmatrix} 1 & 2 & 0 & 0 & 0 \\ 3 & 4 & 5 & 0 & 0 \\ 0 & 6 & 7 & 8 & 0 \\ 0 & 0 & 9 & 1 & 2 \\ 0 & 0 & 0 & 3 & 4 \end{bmatrix}, \quad \mathbf{d} = \begin{bmatrix} 1 \\ 2 \\ 3 \\ 4 \\ 5 \end{bmatrix}$$

■ SOLUTION

Entering A and d into MATLAB,

To solve the tridiagonal linear system for x,

```
x = tridiagonal(A,d)
```

This yields the result

x =

-0.7229 0.8614 0.1446 -0.3976 1.5482

Tridiagonal Matrix Algorithm (Thomas Algorithm)

A tridiagonal linear system is one of the form

We can define the x and d vectors as

$$\mathbf{x} = \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_{n-1} \\ x_n \end{bmatrix}, \quad \mathbf{d} = \begin{bmatrix} d_1 \\ d_2 \\ \vdots \\ d_{n-1} \\ d_n \end{bmatrix}$$

and the $n \times n$ triadiagonal matrix¹, A, as

$$\mathbf{A} = \begin{bmatrix} b_1 & c_1 \\ a_1 & b_2 & c_2 \\ & a_2 & \ddots & \ddots \\ & & \ddots & \ddots & c_{n-2} \\ & & & a_{n-2} & b_{n-1} & c_{n-1} \\ & & & & a_{n-1} & b_n \end{bmatrix}$$
 (1)

Now we can write the tridiagonal linear system as

$$\mathbf{A}\mathbf{x} = \mathbf{d} \tag{2}$$

where $\mathbf{A} \in \mathbb{R}^{n \times n}$ and $\mathbf{x}, \mathbf{d} \in \mathbb{R}^n$.

The **tridiagonal matrix algorithm** (also known as the **Thomas algorithm**) is an algorithm that can efficiently solve the tridiagonal linear system (given by Eq. (2)) for x. This algorithm uses three vectors, a, b, and c, which we

$$\mathbf{A} = \begin{bmatrix} a_1 & b_1 \\ c_1 & a_2 & b_2 \\ & c_2 & \ddots & \ddots \\ & & \ddots & \ddots & \\ & & \ddots & \ddots & b_{n-2} \\ & & & c_{n-2} & a_{n-1} & b_{n-1} \\ & & & & c_{n-1} & a_n \end{bmatrix}$$

However, when dealing with the tridiagonal matrix algorithm, a convention similar to the one in Eq. (1) is used almost exclusively. However, the convention that most sources have has the a_i 's ranging from a_2 to a_n , which is extremely inconvenient from an algorithmic standpoint; therefore, I defined them here as ranging from a_1 to a_{n-1} , and this is also reflected in Algorithm 1.

¹ In many references, a tridiagonal matrix is defined with the convention

define as [1]

$$\mathbf{a} = \begin{bmatrix} a_1 \\ \vdots \\ a_{n-1} \end{bmatrix}, \quad \mathbf{b} = \begin{bmatrix} b_1 \\ \vdots \\ b_n \end{bmatrix}, \quad \mathbf{c} = \begin{bmatrix} c_1 \\ \vdots \\ c_{n-1} \end{bmatrix}$$

The tridiagonal matrix algorithm is shown below [1-3].

22 end

23 return x

Algorithm 1: Tridiagonal matrix algorithm (Thomas algorithm).

```
1 Given: A, x, d
   // determines n (where \mathbf{A} \in \mathbb{R}^{n \times n})
 n = \operatorname{size}(\mathbf{A}, 1)
 3 Preallocate vectors of size n \times 1 to store b and x.
4 Preallocate vectors of size (n-1) \times 1 to store a and c.
   // extracts a from A
 5 for i=2 to n do
 6 a_{i-1} = A_{i,i-1}
 7 end
  // extracts b from A
s for i=1 to n do
 b_i = A_{i,i}
10 end
   // extracts c from A
11 for i=2 to n do
12 c_{i-1} = A_{i-1,i}
13 end
   // forward elimination
14 for i = 1 to n do
      w = a_{i-1}/b_{i-1}
15
      b_i = b_i - wc_{i-1}
    d_i = d_i - wd_{i-1}
18 end
  // backward substitution
19 x_n = d_n/b_n
20 for i = n - 1 to 1 by -1 do
21 x_i = (d_i - c_i x_{i+1})/b_i
```
